1	Interrupts in 8086/8088	1
2	Hardware Interrupts	2
2.1	Procedure	2
3	Software Interrupts	2
3.1	Difference between INT and CALL	2
3.2	Predefined conditional interrupts	3
4	Interrupt Priority	3
4.1	Priority of INTR	3
4.2	Interrupt Nesting	3

1 Interrupts in 8086/8088

- 256 types
- $\text{type} \times 4 = \text{PA of interrupt vector}$
- IVT: first 1KB

2 Hardware Interrupts

- maskable interrupt (INTR)
 - IF = 1, enable
 - STI sets IF, CLI clears IF
 - interrupt requests from external I/O
- non-maskable (NMI)
 - RAM parity check error
 - interrupt from co-processor

2.1 Procedure

- CPU responds to INTR
 - check INTR on the last cycle, INTR and IF = 1
 - CPU sends 2 negative pluses on !INTA pin
 - upon receiving second !INTA, I/O device sends interrupt type on data bus
- CPU executes ISR of INT N
 - reads N from data bus
 - push FR in stack
 - clear IF, TF
 - push CS, IP to stack
 - load ISR entrance
 - upon return, pop IP, CS, FR, returns previous program

3 Software Interrupts

- INT xx
 - e.g. INT 21H DOS service
- exceptions (predefined)
- CPU always responds (ignore IF)

3.1 Difference between INT and CALL

- call far can jump anywhere (within 1MB)
- call is in sequential instructions

- call cannot be masked
- call doesn't save FR
- RETF / RET

3.2 Predefined conditional interrupts

- 00 divide error
- 01 single step
- 03 breakpoint
- 04 signed number overflow

4 Interrupt Priority

- $INT > NMI > INTR$

4.1 Priority of INTR

- software polling, sequence of checking
- hardware checking, location in daisy chain
- interrupt controller (8259) programmable

4.2 Interrupt Nesting

- higher priority interrupts lower priority
- STI: controls whether responds to interrupt (IF)
- EOI: service complete (IS in 8259)
